CLIMATE TRENDS AND VARIATIONS BULLETIN

This bulletin summarizes recent climate data and presents it in a historical context. It first examines the national average temperature for the season and then highlights interesting regional temperature information.

Over the past decade, precipitation monitoring technology has evolved and Environment and Climate Change Canada (ECCC) and its partners implemented a transition from manual observations to using automatic precipitation gauges. Extensive data integration is required to link the current precipitation observations to the long term historical manual observations. The update and reporting of historical adjusted precipitation trends and variations will be on temporary hiatus pending the extensive data reconciliation, and resumed thereafter. ECCC remains committed to providing credible climate data to inform adaptation decision making, while ensuring the necessary data reconciliation occurs as monitoring technology evolves.

NATIONAL TEMPERATURE

The national average temperature for the spring (March-May) of 2019 was 1.6°C above the baseline average (defined as the mean over the 1961–1990 reference period), based on preliminary data, which is the 13th warmest observed spring since nationwide recording began in 1948. The warmest spring occurred in 2010, when the national average temperature was 4.0°C above the baseline average. The coldest spring occurred in 1974, when the national average temperature was 2.0°C below the baseline average. The temperature departures map shows that Yukon, Northwest Territories, Nunavut, most of British Columbia, the northern parts of Alberta, Saskatchewan, Manitoba, Quebec and Newfoundland and Labrador experienced temperatures above the baseline average. Meanwhile, the southern parts of Alberta, Saskatchewan, Manitoba, Quebec, much of Ontario and Atlantic Canada experienced spring temperatures below the baseline average. Spring temperatures were near the baseline average in the remainder of the country.

The time series graph shows that averaged spring temperatures across the country have fluctuated from year to year over the 1948–2019 period. The linear trend indicates that spring temperatures averaged across the nation have warmed by 1.7°C over the past 72 years.
REGIONAL TEMPERATURE

When examined on a regional basis, average spring temperatures for 2019 were among the 10 warmest recorded since 1948 for five of the eleven climate regions: Yukon/North B.C. Mountains (2\textsuperscript{nd} warmest at 4.1°C above average), Mackenzie District (3\textsuperscript{rd} warmest at 4°C above average), Arctic Tundra (3\textsuperscript{rd} warmest at 3.4°C above average), Arctic Mountains and Fiords (5\textsuperscript{th} warmest at 3.3°C above average) and the Pacific Coast (9\textsuperscript{th} warmest at 1.4°C above average). Average spring temperatures for 2019 were among the 10 coldest on record for one of the eleven climate regions: Great Lakes/St. Lawrence (10\textsuperscript{th} coldest at 1.1°C below average).

All eleven climate regions exhibit positive trends for spring temperatures over the 72 years of record.
