# Draft guidance document on the collection and analysis of disaggregated data in clinical trials

# 1 Foreword

2 Guidance documents provide assistance to industry and health care professionals on how to comply with  
3 governing statutes and regulations. They also provide guidance to Health Canada staff on how mandates and  
4 objectives should be met fairly, consistently and effectively.

5 Guidance documents are administrative, not legal, instruments. This means that flexibility can be applied.  
6 However, to be acceptable, alternate approaches to the principles and practices described in this document  
7 must be supported by adequate justification. They should be discussed in advance with the relevant program  
8 area to avoid the possible finding that applicable statutory or regulatory requirements have not been met.

9 Health Canada reserves the right to request information or material, or define conditions not specifically  
10 described in this document, to help us adequately assess the safety, efficacy or quality of a therapeutic  
11 product. We are committed to ensuring that such requests are justifiable and that decisions are clearly  
12 documented.

13 This document should be read in conjunction with the accompanying notice and the relevant sections of  
14 the *Food and Drug Act* and its *Regulations* and other applicable guidance documents.

15

## 40 Overview

### 41 Background

42 This guidance will help sponsors interpret amendments to the *Food and Drug Regulations* (regulations)  
43 requiring them to submit clinical trial data disaggregated by sex, age and race/ethnicity if they have already  
44 done so as required by existing legislation or regulation in the [United States](#) or [Europe](#).

45 It is standard practice to collect disaggregated subgroup data during drug development (for example, refer to  
46 the international standards outlined [ICH M4E\(R2\)](#)).

47 This guidance:

- 48 • sets out Health Canada's expectations
- 49 • supports our efforts to be transparent
- 50 • ensures that the provisions in the regulations on disaggregated data are interpreted consistently

51 The first part of this guidance document outlines how to comply with regulatory requirements for submitting  
52 disaggregated data. The second part of this guidance provides information and best practices related to  
53 collecting, analyzing and reporting on disaggregated data in clinical evidence, where applicable.

54 Disaggregated data is data obtained by breaking down aggregated datasets into subcategories. These  
55 subcategories are based on factors such as sex, age, race/ethnicity, co-morbidities and/or other patient  
56 demographics.

57 Disaggregating data is an important approach to data collection and analysis in drug development, as it:

- 58 • allows sponsors and Health Canada to assess the efficacy and safety of drug products in different  
59 subgroups
- 60 • ensures there is consistency with the overall results, where feasible
- 61 • indicates where more focused post-market monitoring may be needed to further verify safety and  
62 efficacy in certain populations after products are approved for sale in Canada

63 The collection and analysis of disaggregated data is at the core of Health Canada's [sex and gender-based  
64 analysis plus \(SGBA Plus\) mandate](#).

65 SGBA Plus is an analytical process used to assess:

- 66 • how diverse groups of women, men and non-binary people may experience policies, programs and  
67 initiatives
- 68 • differences in how groups of people (subgroups) react to a specific drug in terms of both efficacy and  
69 safety

70 The "plus" in SGBA Plus acknowledges that SGBA goes beyond biological (sex) and socio-cultural (gender)  
71 differences. It indicates the importance of intersectionality, which refers to the multiple factors that intersect  
72 to make us who we are, such as:

- 73 • sex
- 74 • age
- 75 • race
- 76 • gender
- 77 • geographic location

## 78 Policy objective

79 Clinical trial participants should represent the population who will be using the drug. This is important as  
80 intrinsic (genetic, physiologic) and extrinsic (cultural, environmental) characteristics of a population, including  
81 age, sex and race/ethnicity, can lead to different treatment effects. Some, but not all, of the intrinsic and  
82 extrinsic factors that can impact a person's response to a drug product are known.

83 Patient populations are also often heterogeneous across many factors (for example, sex, age and race).

84 These factors highlight the importance of recruiting representative clinical trial participants so that data can  
85 be disaggregated and analyzed meaningfully by subgroups of interest (for example, sex, age, race, co-  
86 morbidities, and medication use).

87 Health Canada is leveraging experience in other jurisdictions by aligning with existing legislation and  
88 regulations of the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA).

89 Learn more about intrinsic and extrinsic differences in the following guidance and studies:

- 90 • [ICH E5: Ethnic factors in the acceptability of foreign data](#) (ICH Harmonised Tripartite Guideline, PDF)
- 91 • [ICH E8: General considerations for clinical studies](#) (PDF)

## 92 Policy statement

93 The amendments to the regulations are intended to:

- 94 • receive disaggregated data and subgroup analyses that can help assess differences in key efficacy  
95 and/or safety parameters between clinically relevant, prognostic subgroups
- 96 • increase transparency by assessing and reporting on the diversity of clinical trial participants for each  
97 drug product

## 98 Scope and application

99 This draft guidance document is for sponsors who will be applying to Health Canada for market authorization  
100 for a drug for human use.

101 The scope of this guidance document includes drugs for human use. These drugs are regulated by the Health  
102 Products and Food Branch in accordance with the *Food and Drugs Act* and the regulations.

## 103 Terms and definitions

104 **Disaggregated data:** Data obtained by breaking down large-scale or aggregated datasets into subcategories,  
105 such as sex, age and race/ethnicity, or a combination of these (and/or other) subcategories.

106 **Disaggregated data plan:** A plan designed to support the collection and assessment of disaggregated data by  
107 age, sex, racial/ethnic groups and associated covariates. The plan is used to establish whether and how a  
108 treatment may affect the benefit-risk profile of specific subgroups.

109 **Gender:** The socially constructed roles, behaviours, expressions and identities of girls, women, boys, men and  
110 gender-diverse people. It influences how people perceive themselves and each other, how they act and  
111 interact, and the distribution of power and resources in society.

112 Gender identity is not confined to a binary (girl/woman, boy/man) or static. It exists along a continuum and  
113 can change over time.

114

115 There is considerable diversity in:

- 116 • how individuals and groups understand, experience and express gender through the roles they take
- 117 on
- 118 • the expectations placed on them
- 119 • a person's relations with others
- 120 • the complex ways that gender is institutionalized in society

121 Please refer to the following definition by the Canadian Institute of Health Research:

- 122 • [What is gender? What is sex?](#)

123 **Heterogeneity assessment:** An evaluation examining whether differences in treatment efficacy or safety are  
124 anticipated between subgroups of the overall study population. This assessment is a key aspect of clinical  
125 trial protocol design. It should describe the measures taken to establish whether there are, or could be,  
126 clinically important age, sex and racial/ethnic differences in response to study treatment.

127 **Sex:** A set of biological attributes in humans and animals. It is mainly associated with physical and  
128 physiological features, such as chromosomes, gene expression, hormone levels and function, and  
129 reproductive/sexual anatomy.

130 Sex is usually categorized as female or male, but there is variation in the biological attributes that comprise  
131 sex and how those attributes are expressed.

132 Sex differs from gender, which refers to the socially constructed roles, behaviours, expressions and identities  
133 of girls, women, boys, men and gender-diverse people.

134

## 135 Regulatory Requirements

### 136 Submitting disaggregated data

137 Health Canada now requires that new drug submissions (NDS) and Level I supplements to new drug  
138 submissions (SNDS) for human drugs include clinical evidence that has been disaggregated.

139 For information on these requirements, please consult:

- 140 • [Post-notice of compliance changes: Safety and efficacy document](#)

141 As a first step, these requirements will apply when sponsors:

- 142 • have submitted clinical data disaggregated by sex, age and race/ethnicity
  - 143 ○ based on legislative and/or regulatory requirements for market authorization set out by the
  - 144 U.S. Food and Drug Administration (FDA) or the European Medicines Agency (EMA)

145 We expect sponsors to conduct additional subgroup analyses when relevant (for example, co-morbidities,  
146 current and past medication use). This is standard practice in clinical trial design.

147 Currently:

- 148 • FDA requires data disaggregated by sex, race/ethnicity and age
- 149 • EMA requires data on sex and age, along with a justification if that data is not available

150 When both datasets are available, we prefer FDA data for sex, age and race/ ethnicity where possible.

151 When sponsors have not previously submitted disaggregated data to the FDA and/or EMA, we strongly  
152 encourage them to provide disaggregated data to Health Canada, where feasible. You are to provide a  
153 justification if your submission does not include this data. The justification should include the rationale for  
154 why disaggregated data are not applicable to the current submission, and/or why they have not been  
155 included.

156 In general, clinical trials are not designed to assess efficacy and safety in subgroups with statistical rigour. Nor  
157 do they have a sufficient number of participants to facilitate such an assessment. For these reasons, we  
158 understand that the results from such analyses are descriptive, exploratory in nature and should be  
159 interpreted with caution.

## 160 Disaggregated data best practices

### 161 About disaggregated data best practices

162 Recruiting diverse clinical trial participants and conducting relevant subgroup analyses remains critically  
163 important to ensure the possibility of determining:

- 164 • whether differences between subgroups exist based on all of the clinical evidence
- 165 • if further monitoring after the drug reaches the market is necessary (where feasible and applicable)
- 166 • whether the clinical trial population mirrors the full diversity of the population that will use the drug  
167 product being tested

168 The collection and analysis of disaggregated data is a key aspect in all phases of a health product's life cycle:

- 169 • study design
- 170 • dose selection
- 171 • testing and evaluation
- 172 • clinical validation
- 173 • risk analysis and management
- 174 • transparency and reporting
- 175 • post-market safety monitoring

### 176 Considerations in protocol design

177 This section outlines information to consider in clinical trial protocol design for drugs for human use,  
178 especially Phase 3 and 4 trials. Such information will help sponsors recruit diverse clinical trial participants  
179 and plan for appropriate subgroup analyses.

180 As a standard practice, the diversity of clinical trial participants should reflect the population that will use the  
181 drug. Before an application is submitted for market authorization in Canada, drugs should be evaluated in  
182 participants who represent the full range of persons likely to receive the product, whenever possible.

183 For example:

- 184 • [Considerations for inclusion of women in clinical trials and analysis of sex differences](#)

185 It is also important that clinical trial results are applicable to the populations likely to use the product.  
186 Evidence that can help evaluate benefit-risk profiles of specific subgroups is generated by collecting:

- 187 • disaggregated data on the age, sex and race/ethnicity of participants
- 188 • other clinically relevant baseline characteristics

189 As mentioned, differences in age, sex and race/ethnicity may contribute to different efficacy and safety  
190 profiles for drug products, for example:

- 191 • [sex differences in pharmacokinetics and pharmacodynamics may impact drug safety and  
192 effectiveness in some contexts](#)

193 Similarly, data from diverse racial/ethnic groups may necessitate different treatment parameters, for  
194 example:

- 195 • different dosing recommendations for therapeutics, such as:
  - 196 ○ lower initial starting dose of statins in [Asian patients](#) or
  - 197 ○ higher doses of tacrolimus in [Black patients](#)

198 It is understood that racial/ethnic differences in drug metabolism are largely attributable to genetic and  
199 genomic differences. These differences can directly influence drug absorption, distribution, metabolism and  
200 excretion.

201 Genetic and genomic factors influence the overall enzyme make-up of an individual, and certain mutations or  
202 gene variants are more common in specific ethnic groups. This contributes to pharmacokinetic variability in  
203 these subgroups. For example, gene variants affecting transporter proteins impact the safety and efficacy of  
204 statins. Similarly, gene variants also affect expression of enzymes, which influence the bioavailability and  
205 clearance of tacrolimus.

206 For more information:

- 207 • [The pharmacogenomics of statins](#)
- 208 • [Safety and efficacy of statins in Asians](#)
- 209 • [Sex differences in pharmacokinetics and pharmacodynamics](#)
- 210 • [Genotype-guided tacrolimus dosing in African American kidney transplant recipients](#)
- 211 • [Impact of ABCG2 and SLCO1B1 polymorphisms on pharmacokinetics of rosuvastatin, atorvastatin,  
212 and simvastatin acid in Caucasian and Asian subjects: A class effect?](#)
- 213 • [African-American race modifies the influence of tacrolimus concentrations on acute rejection and  
214 toxicity in kidney transplant recipients](#)

## 215 Heterogeneity assessment

216 A heterogeneity assessment (HA) is an evaluation examining whether differences in treatment efficacy or  
217 safety are anticipated between subgroups of the overall study population. The HA should describe the  
218 measures taken to establish whether there are, or could be, clinically important age, sex and racial/ethnic  
219 differences in response to the drug product being tested.

220 The U.S. Food and Drug Administration (FDA) outlines a similar approach in the following:

- 221 • [Diversity plans to improve enrollment of participants from underrepresented racial and ethnic  
222 populations in clinical trials: Draft guidance for industry](#)

223 To ensure diverse subgroups are meaningfully considered in a drug product's development and testing, an  
224 overarching HA should be performed at the start of the clinical development program. This HA will determine  
225 how best to approach clinical development and trial design.

226 Sponsors should update the HA as needed throughout the development process as more information on  
227 sources of heterogeneity is learned from early phase trials. These additional sources of heterogeneity may  
228 require further supporting data.

229 If the HA indicates that treatment differences are not anticipated among subgroups, enrollment should still  
230 be broad and reflect disease epidemiology. Broad enrollment of representative populations:

- 231 • permits subgroup analyses
- 232 • may enable the assessment of effect consistency across trials, where appropriate

233 Learn more:

- 234 • [ICH E9: Statistical principles for clinical trials](#)

235 Alternatively, if the HA or evidence from previous or ongoing studies indicates meaningful differences in any  
236 of the subgroups studied, sponsors should consider such differences when planning, designing and analyzing  
237 individual studies within the clinical development program. This includes plans to recruit enough

238 representative patients to be able to analyze the benefit-risk profile in the relevant subgroups, where  
239 possible.

240 Learn more in the following EMA guidance document:

- 241 • [Guideline on the investigation of subgroups in confirmatory clinical trials](#)

242 If there is a possibility that there could be differing treatment responses between subgroups, sponsors should  
243 explore the potential reasons for the heterogeneity and describe this in the trial(s) design(s) stage. Analyses  
244 should consider these potential differences. Note: In some cases, this type of analysis may only be feasible  
245 when analyzing all of the clinical evidence and/or in post-market monitoring.

246 Known factors that may affect the safety and efficacy of the drug product between subgroups should inform  
247 the HA. Sponsors should consider disease pathophysiology, previously identified predictive or prognostic  
248 factors, biological plausibility, epidemiology of the condition and/or therapeutic drug class.

249 Information for certain diseases may be limited, making it difficult to assess potential subgroup-specific  
250 heterogeneity. To supplement their HA, sponsors should find relevant data sources in academic literature  
251 and/or seek out real world evidence (RWE).

252 Sponsors may use non-clinical studies to provide supportive data. For example, pharmacology and toxicology  
253 studies conducted in male and female animals can indicate potential sex-related differences in concentration  
254 response, safety or efficacy.

255 To understand how non-clinical studies can support and inform clinical trial evidence, consult ICH harmonized  
256 guidelines for clinical trials, such as:

- 257 • [ICH E8](#) : General considerations for clinical studies
- 258 • [ICH S9](#) : Nonclinical evaluation for anticancer pharmaceuticals
- 259 • [ICH S11](#) : Nonclinical safety testing in support of development of paediatric pharmaceuticals
- 260 • [ICH M3\(R2\)](#) : Nonclinical safety studies for the conduct of human clinical trials for pharmaceuticals

261 As the HA informs the study design and enrollment plan, sponsors should include it in their submission  
262 material for clinical trial applications and/or market authorization.

263 Of note, the contents of the current guidance apply to preceding documents such as:

- 264 • [Guidance document for clinical trial sponsors: Clinical trial applications](#)

## 265 Disaggregated data plan

266 A disaggregated data plan (DDP) is used to determine the parameters for disaggregated data collection and  
267 subsequent analyses. By supporting the collection and assessment of disaggregated data by age, sex,  
268 racial/ethnic groups and other associated covariates, the DDP helps sponsors establish if and how a  
269 treatment may affect the benefit-risk profile of specific subgroups.

270 The content of the DDP should be based on the findings of the HA. To support subgroup analysis, sponsors  
271 should aim to enroll representative proportions of age, sex and racial/ethnic subgroups that are consistent  
272 with those who will use the drug product or as indicated by the HA.

273 Otherwise, sponsors should either:

- 274 • justify how the enrollment criteria provide acceptable representation for the intended population or
- 275 • explain if a factor other than age, sex or race/ethnicity is a primary driver of heterogeneity upon
- 276 which the disaggregated data plan should be based

277 These recommendations generally apply to all trials, but more feasibly, are targeted to phase 3 and 4 studies,  
278 as these trials tend to enroll more patients than earlier trials.

279 The DDP and data submission should describe:

- 280 • the number of participants planned for each study
- 281 ○ outline how the sponsor will collect subgroup data throughout the product life cycle in the  
282 description
- 283 • how age, sex and race/ethnicity, as well as other related covariates, will be assessed
- 284 • how potential differences will be taken into account
- 285 ○ for example, by enriched or restricted enrollment (by selecting for or limiting certain patient  
286 characteristics), confirmatory trials and so on, as applicable

287 This description will maximize early discussions of subgroups and establish a strategy for considering diverse  
288 subgroups before the trials begin, if required. For example:

- 289 • if it is known early on that the treatment is only effective in certain subgroups, then trial enrollment  
290 could be restricted to those populations
- 291 • if a factor affecting subgroups is known to be prognostic in value, then treatment groups may be  
292 balanced for this factor at the randomization stage through stratification

293 Sponsors should capture the details of both the HA and DDP, including enrollment strategies, in the  
294 appropriate sections of the clinical study protocol and statistical analysis plan (SAP). Include applicable  
295 results, analyses and discussion in the clinical study report (CSR).

296 For data submitted in the CSR, sponsors should:

- 297 • capture disaggregated data for enrolled and completed participants
- 298 ○ population pharmacokinetic analyses often include age and sex as co-variates
- 299 ○ race/ethnicity should also be included as it may affect the interpretation of drug product  
300 efficacy and/or safety in subgroups as well as clinical parameters of use
- 301 ○ pharmacometric modelling and analyses are encouraged
- 302 • present key efficacy and safety data by age, sex and race/ethnicity and describe whether any  
303 treatment modifications (for example, of dose or dosing regimen) are needed for subgroups
- 304 ○ clinically relevant findings may be reflected in the product labelling as per Health  
305 Canada's [guidance on the product monograph](#)

306 We encourage sponsors to engage in discussions with the relevant Health Canada directorate early on in the  
307 process. Sponsors may also ask for feedback during pre-clinical trial application meetings and/or in pre-  
308 submission meetings for a new drug submission (NDS) or supplement to a new drug submission (SNDS).

309 More details on pre-submission meetings for NDS or SNDS are included in the following guidance document:

- 310 • [Management of drug submissions and applications](#)

## 311 Data collection and analysis

312 Important considerations for collecting and analyzing disaggregated data include key subgroups and  
313 parameters for analysis, interpretation and reporting.

314 Sponsors should pre-specify the strategy for enrolling and assessing subgroup data in the protocol before  
315 they enroll clinical trial participants.

### 316 Key subgroups

317 The variables that should be considered when designing clinical trials are specific to the particular therapeutic  
318 area in which the study is being conducted. However, there are key considerations for including clinical trial  
319 participants who are diverse in sex, age and race/ethnicity. Of note, it is understood that representative  
320 enrollment of age, sex, and racial/ethnic subgroups may pose challenges.

321 Sponsors should consider potential reasons if they have difficulty recruiting certain populations. In this case,  
322 you should devise strategies to enhance enrollment and retention in the subgroups of interest, as needed.

323 Learn more by consulting the following guidance from the U.S. Food and Drug Administration (FDA):

- 324 • [Enhancing the diversity of clinical trial populations - Eligibility criteria, enrollment practices and trial](#)  
325 [designs](#)

#### 326 Sex

327 Include a representative number of females and males in clinical trials, as applicable to the intended  
328 population that will use the drug.

329 To identify and account for potential sex-related differences when planning clinical trials, we recommend  
330 that females (such as those who are of child-bearing age or menopausal) be included as early as possible in  
331 the clinical trial research stage.

332 For details on what to consider when collecting and analyzing sex-related data, please consult the following  
333 guidance document:

- 334 • [Considerations for inclusion of women in clinical trials and analysis of sex differences](#)

#### 335 Age

336 Age groups that reflect the clinical prevalence of disease should be adequately represented. This permits the  
337 analysis of various age groups, as needed.

338 We recommend that detailed disaggregation of age groups be provided. For example, to better inform  
339 treatment decisions for geriatric patients in clinical practice, older patients may be grouped into ages 65 to  
340 74, 75 to 84 and over 85 rather than the combining all age groups into a 65+ category.

341 Learn more in the following guidance documents:

- 342 • [ICH E7: Studies in support of special populations: Geriatrics](#)
- 343 • [FDA: Inclusion of older adults in cancer clinical trials](#)

344 Detailed disaggregation of pediatric age subgroups corresponding to developmental biology specific to drug  
345 product pharmacology is also recommended, for example:

- 346 • preterm newborn infants
- 347 • term newborn infants (0 to 27 days)
- 348 • infants and toddlers (28 days to 23 months)
- 349 • children (2 to 11 years)
- 350 • adolescents (12 to 16/18 years)

351 Neurocognitive development, puberty, hormonal changes and weight are some examples of processes or  
352 characteristics that should be considered when planning, analyzing and reporting pediatric subgroup data.

353 Learn more:

- 354 • [ICH E11: Clinical investigation of medicinal products in the pediatric population](#)

### 355 Race/ethnicity

356 To assess potential race/ethnicity-related differences for the population who will use the drug, we  
357 recommend that representative proportions of subjects be enrolled in clinical trials. Note that the following  
358 will vary:

- 359 • specific race/ethnicity subgroups depending on the population that is expected to use the drug
- 360 • the geopolitical context where the clinical trials will be held and where the application for market  
361 authorization will be submitted

362 For trials conducted in Canada, self-reported race/ethnicity should follow [Statistics Canada classifications](#).  
363 Current classifications for population groups include:

- 364 • Arab
- 365 • Black
- 366 • White
- 367 • Filipino
- 368 • Korean
- 369 • Chinese
- 370 • Japanese
- 371 • West Asian
- 372 • South Asian
- 373 • Latin American
- 374 • Southeast Asian
- 375 • other group (specify)

376 Indigenous Peoples comprising First Nations, Métis and Inuit populations are another key population group in  
377 Canada. Respondents should be able to select the categories that apply.

378 For trials conducted elsewhere, sponsors should follow the reporting categories of the respective national  
379 regulatory body, if available. More detailed racial/ethnic data may be required in certain conditions with  
380 specific hereditary patterns.

381 Reporting standards in different countries will vary, making it difficult to pool data for comparisons.  
382 Consequently, sponsors should clearly define subgroups in their protocols.

### 383 Analyzing, interpreting and reporting disaggregated data

384 Sponsors should stratify results for key efficacy and safety outcome(s) by age, sex and race/ethnicity, as  
385 applicable. These results should be interpreted with caution, given the potential for a limited number of  
386 participants in some subgroups and for confounding by other factors.

387 For guidance on analyzing and interpreting subgroup data, please refer to:

- 388 • [Section 5.7, "Subgroups, interactions and covariates" of ICH E9](#)

389 If the differences observed among various subgroups are interpretable and considered clinically relevant,  
390 sponsors should investigate if the results are biologically plausible or may have occurred by chance. Following  
391 a thorough assessment, sponsors should address those results that are biologically plausible and thus may  
392 impact the benefit-risk profile of the product in the relevant subgroup(s).

393 In such cases, Health Canada may:

- 394 • request additional data
- 395 • implement terms and conditions
- 396 • recommend specific labelling
- 397 • require additional post-market studies or surveillance
- 398 • require additional risk minimization measures

399 Sponsors should include:

- 400 • a description of methods and approach in the clinical trial protocol and statistical analysis plan (SAP),
- 401 as applicable
- 402 • results, analyses and subsequent discussion in the clinical study report (CSR)

403 To assess the consistency of the efficacy and safety findings across relevant subgroups, sponsors should  
404 present results based on analyses described in the disaggregated data plan (DDP) (and captured in the  
405 appropriate sections of the clinical study protocol and SAP). These should be placed in the appropriate  
406 section of the CSR, if available.

407 In particular, sponsors should also include:

- 408 • a table that presents disaggregated demographic data by treatment group ([ICH M4](#))
- 409 • subgroup results for key measures in the corresponding efficacy and safety sections, as applicable
- 410 • a discussion of differences that are considered clinically relevant and biologically plausible on the  
411 benefit-risk profile specific to age, sex or race/ethnicity, as applicable

## 412 Transparency

413 Health Canada will continue to communicate up-to-date information about drugs for human use. You can  
414 find the following information online:

- 415 • Notice of Compliance ([NOC database](#)): contains NOCs issued for drugs for human and veterinary use
- 416 • [Drug product database](#): contains information about drug identification numbers (DINs) issued for  
417 drugs for human and veterinary use, including the product monograph for human drugs and the  
418 product labelling for veterinary drugs
- 419 • Drug and Health Product Portal: contains [Regulatory Decision Summaries](#) and [Summary Basis of](#)  
420 [Decision documents](#), which describe Health Canada's rationale for the approval of prescription drugs  
421 for human use
- 422 • [Clinical information portal](#): contains the clinical information, including disaggregated data, filed by  
423 sponsors to seek approval of human drugs under Division 8 of the *Food and Drug Regulations* (FDR)

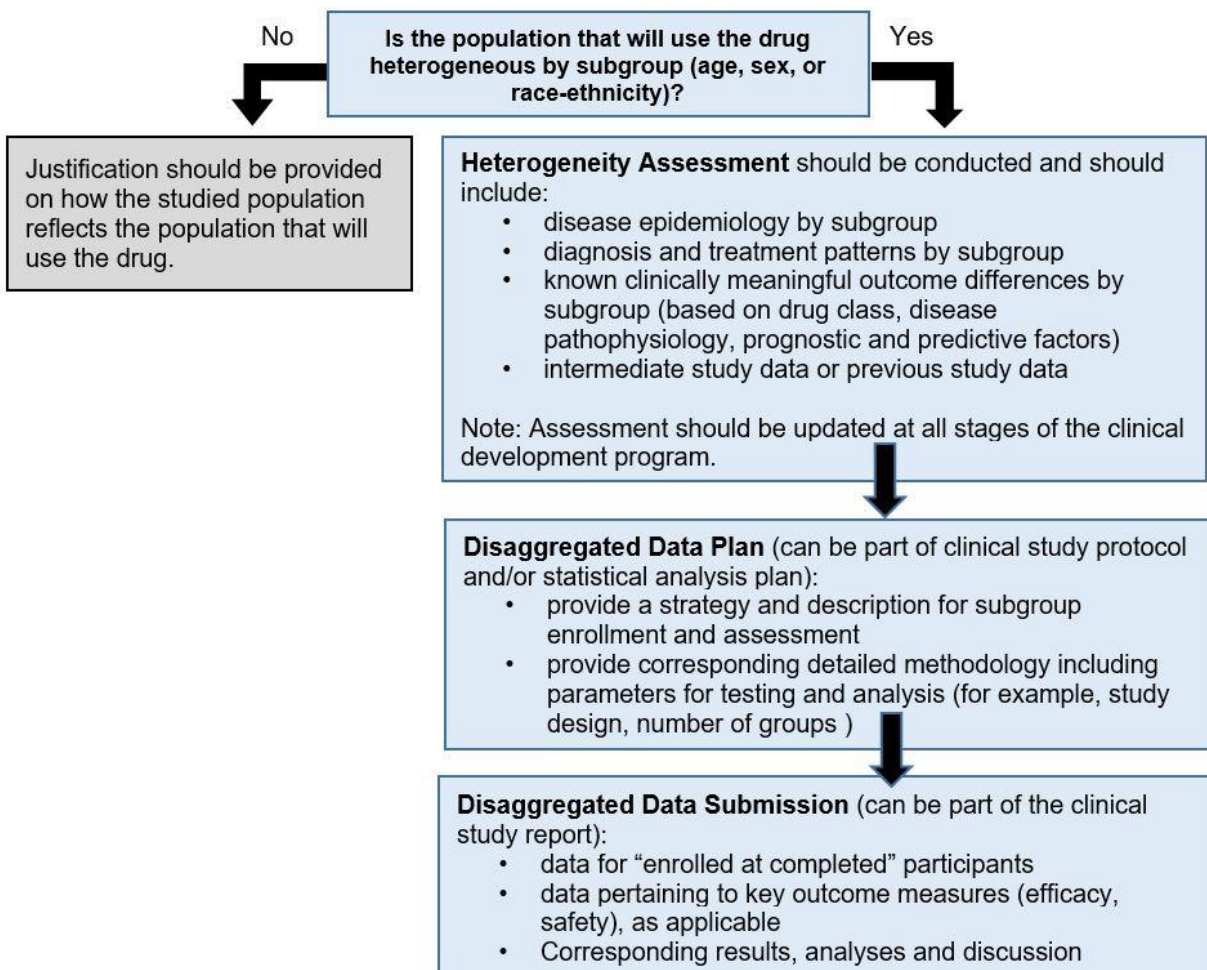

424 Information posted will not contain any confidential business information.

## 425 Disaggregated data decision tree

426 The disaggregated data decision tree outlines key questions to guide clinical trial design, based on the  
427 population that will use the drug being tested. The decision tree summarizes the content in "Considerations  
428 in protocol design".

429 **Figure 1. Decision tree: Study design**
