Abstract

The Public Health Agency of Canada (PHAC) has modernized its approach to physical activity surveillance by broadening its scope to include sedentary behaviour and sleep. The first step was to develop a conceptual framework which covers the full spectrum of physical movement from moderate-to-vigorous intensity physical activity (MVPA) and light intensity physical activity (LPA) to sedentary behaviour and sleep. The framework accounts for the environments in which these behaviours take place (home, work/school, transportation, and community), and applies a socioecological approach to incorporate individual factors and broader built, social, and societal environmental indicators. A visual model of the conceptual framework was created to aid dissemination.

Keywords: motor activity, sedentary behaviour, sleep, framework

Canada has a long series of physical activity surveillance data1 which have received international recognition.2 Canada’s physical activity surveillance system has traditionally focused on measures of leisure-time physical activity. In recent years, there has been a growth in research identifying the independent effects of prolonged sedentary behaviour (e.g., time spent sitting, lying or reclining while awake at a low energy expenditure)3 and inadequate sleep4 on chronic disease.5,6 Further, at the international level, there has been a move away from measuring physical activity through the single lens of leisure-time physical activity and instead examining physical activity behaviours/indicators from across domains of physical activity, such as home, work/school, transportation, and community.4 Finally, a number of scientific systematic reviews and key research papers have been published outlining a broad range of individual, social and environmental correlates or dimensions for physical activity, sedentary behaviour and sleep that were important for consideration with an evidence based surveillance system.6–17 Drawing on these developments, the Public Health Agency of Canada (PHAC) modernized its physical activity surveillance system.

To support the identification and selection of a set of surveillance indicators that would form the foundation of the PHAC’s Physical Activity, Sedentary behaviour and Sleep (PASS) surveillance system, a conceptual framework was developed.18 The conceptual framework included three core components (i.e., behaviours, settings, socioecological approach) and the 24-hour movement spectrum (i.e., physical activity [light, moderate and vigorous], sedentary behaviour and sleep). The first component identified the behaviours of interest: moderate-to-vigorous intensity physical activity (MVPA), light intensity physical activity (LPA), sedentary behaviour, and sleep. The second component looked to incorporate a domain approach to the conceptual framework6 by recognizing the settings in which these behaviours take place including: home; work/school; transportation; and, community. The final component is the use of a socioecological approach recognizing the importance of indicators across multiple levels of influence including: the individual (e.g., age,
sex, ethnicity, socioeconomic status); the family/social environment (e.g., interpersonal relationships, social norms, crime, neighbourhood demographics); and, the built environment (e.g., roadways, buildings, parks, playgrounds, public transit).

To quickly and easily describe the components of the conceptual framework, a visual model was created (Figure 1). This initial visual model, which displayed the components of the conceptual framework using a pyramid format, was presented to experts in the fields of physical activity, sedentary behaviour and sleep, who broadly agreed that it was consistent with current knowledge, and it was used during the selection of the PASS surveillance indicators at a meeting in Ottawa on June 24, 2014. This initial framework lacked descriptions of the types of activities which the indicators were intended to illustrate. Further, the sense of hierarchy in the outcomes implied by the use of a pyramid was not its intended purpose. As a result, a second, visual model (Figure 2) was developed and has been adopted for use alongside the PASS Indicators. The revised visual model includes illustrative examples of the components of the PASS Indicators.

To quickly and easily describe the components of the conceptual framework, a visual model was created (Figure 1). This initial visual model, which displayed the components of the conceptual framework using a pyramid format, was presented to experts in the fields of physical activity, sedentary behaviour and sleep, who broadly agreed that it was consistent with current knowledge, and it was used during the selection of the PASS surveillance indicators at a meeting in Ottawa on June 24, 2014. This initial framework lacked descriptions of the types of activities which the indicators were intended to illustrate. Further, the sense of hierarchy in the outcomes implied by the use of a pyramid was not its intended purpose. As a result, a second, visual model (Figure 2) was developed and has been adopted for use alongside the PASS Indicators. The revised visual model includes illustrative examples of the components of the PASS Indicators.

The visual model illustrates the proposed depth and breadth of the PHAC’s modernized PASS surveillance system. Work to ensure data development and reporting are undertaken in such a way that all areas of the conceptual framework are meaningfully represented is part of the PHAC’s ongoing surveillance activities. In addition, both the visual model and the conceptual framework communicate the PHAC’s approach to PASS surveillance to other international and domestic governmental partners working in surveillance and policy, and to researchers for their contribution and critical appraisal.
